

### Abstract

We present a federated learning framework for both weakly-supervised classification and survival prediction on whole slide images and validate our approach on three different computational pathology tasks, using multi-institutional data from the TCGA and Brigham and Women's Hospital. Our approach is privacy preserving, does not require manual annotations during training, is interpretable and can be applied at scale.

### Motivation

- Accurate, robust AI predictive models often require large amounts of diverse, high-quality labeled data, which can be difficult or impossible to curate at a single institution.
- Federated learning allows machine learning models to be developed on multi-institutional data without requiring direct data sharing, alleviating the burden of navigating around many challenges of sharing sensitive patient data and large cohorts of histopathology images at the tera- or peta-byte scale.
- There is a need for the development and validation of federated learning algorithms for a wide range of computational pathology tasks.

### Weakly-supervised learning on WSIs

First, the tissue regions of each WSI are segmented and divided into patches and encoded by a pretrained CNN into low-dimensional embeddings  $\{z_m\}$ ,  $z_m \in \mathbb{R}^{1024}$ . This results in each WSI being described by a matrix of patch embeddings:  $H_j \in \mathbb{R}^{M_j \times 1024}$ , where  $M_j$  is the number of patches in the  $j^{th}$  WSI. After projecting  $\{z_{j,m}\}$  into  $\{h_{j,m}\}$ ,  $h_{j,m} \in \mathbb{R}^{512}$ , the contribution of each patch  $a_{j,m}$  is given by:

$$a_{j,m} = \frac{\exp\{\mathbf{W}_a (\tanh(\mathbf{V}_a \mathbf{h}_{j,m}^T) \odot \text{sigm}(\mathbf{U}_a \mathbf{h}_{j,m}^T))\}}{\sum_{m=1}^{M_j} \exp\{\mathbf{W}_a (\tanh(\mathbf{V}_a \mathbf{h}_{j,m}^T) \odot \text{sigm}(\mathbf{U}_a \mathbf{h}_{j,m}^T))\}}$$

where  $\mathbf{W}_a$ ,  $\mathbf{U}_a$  and  $\mathbf{V}_a$  are learnable network parameters. Using weighted average pooling, the WSI is in turn described by  $\mathbf{h}_{bag_j} \in \mathbb{R}^{512}$ :

$$\mathbf{h}_{bag_j} = \text{Attn-pool}(\mathbf{A}_j, \mathbf{H}_j) = \sum_{m=1}^{M_j} a_{j,m} \mathbf{h}_{j,m}$$

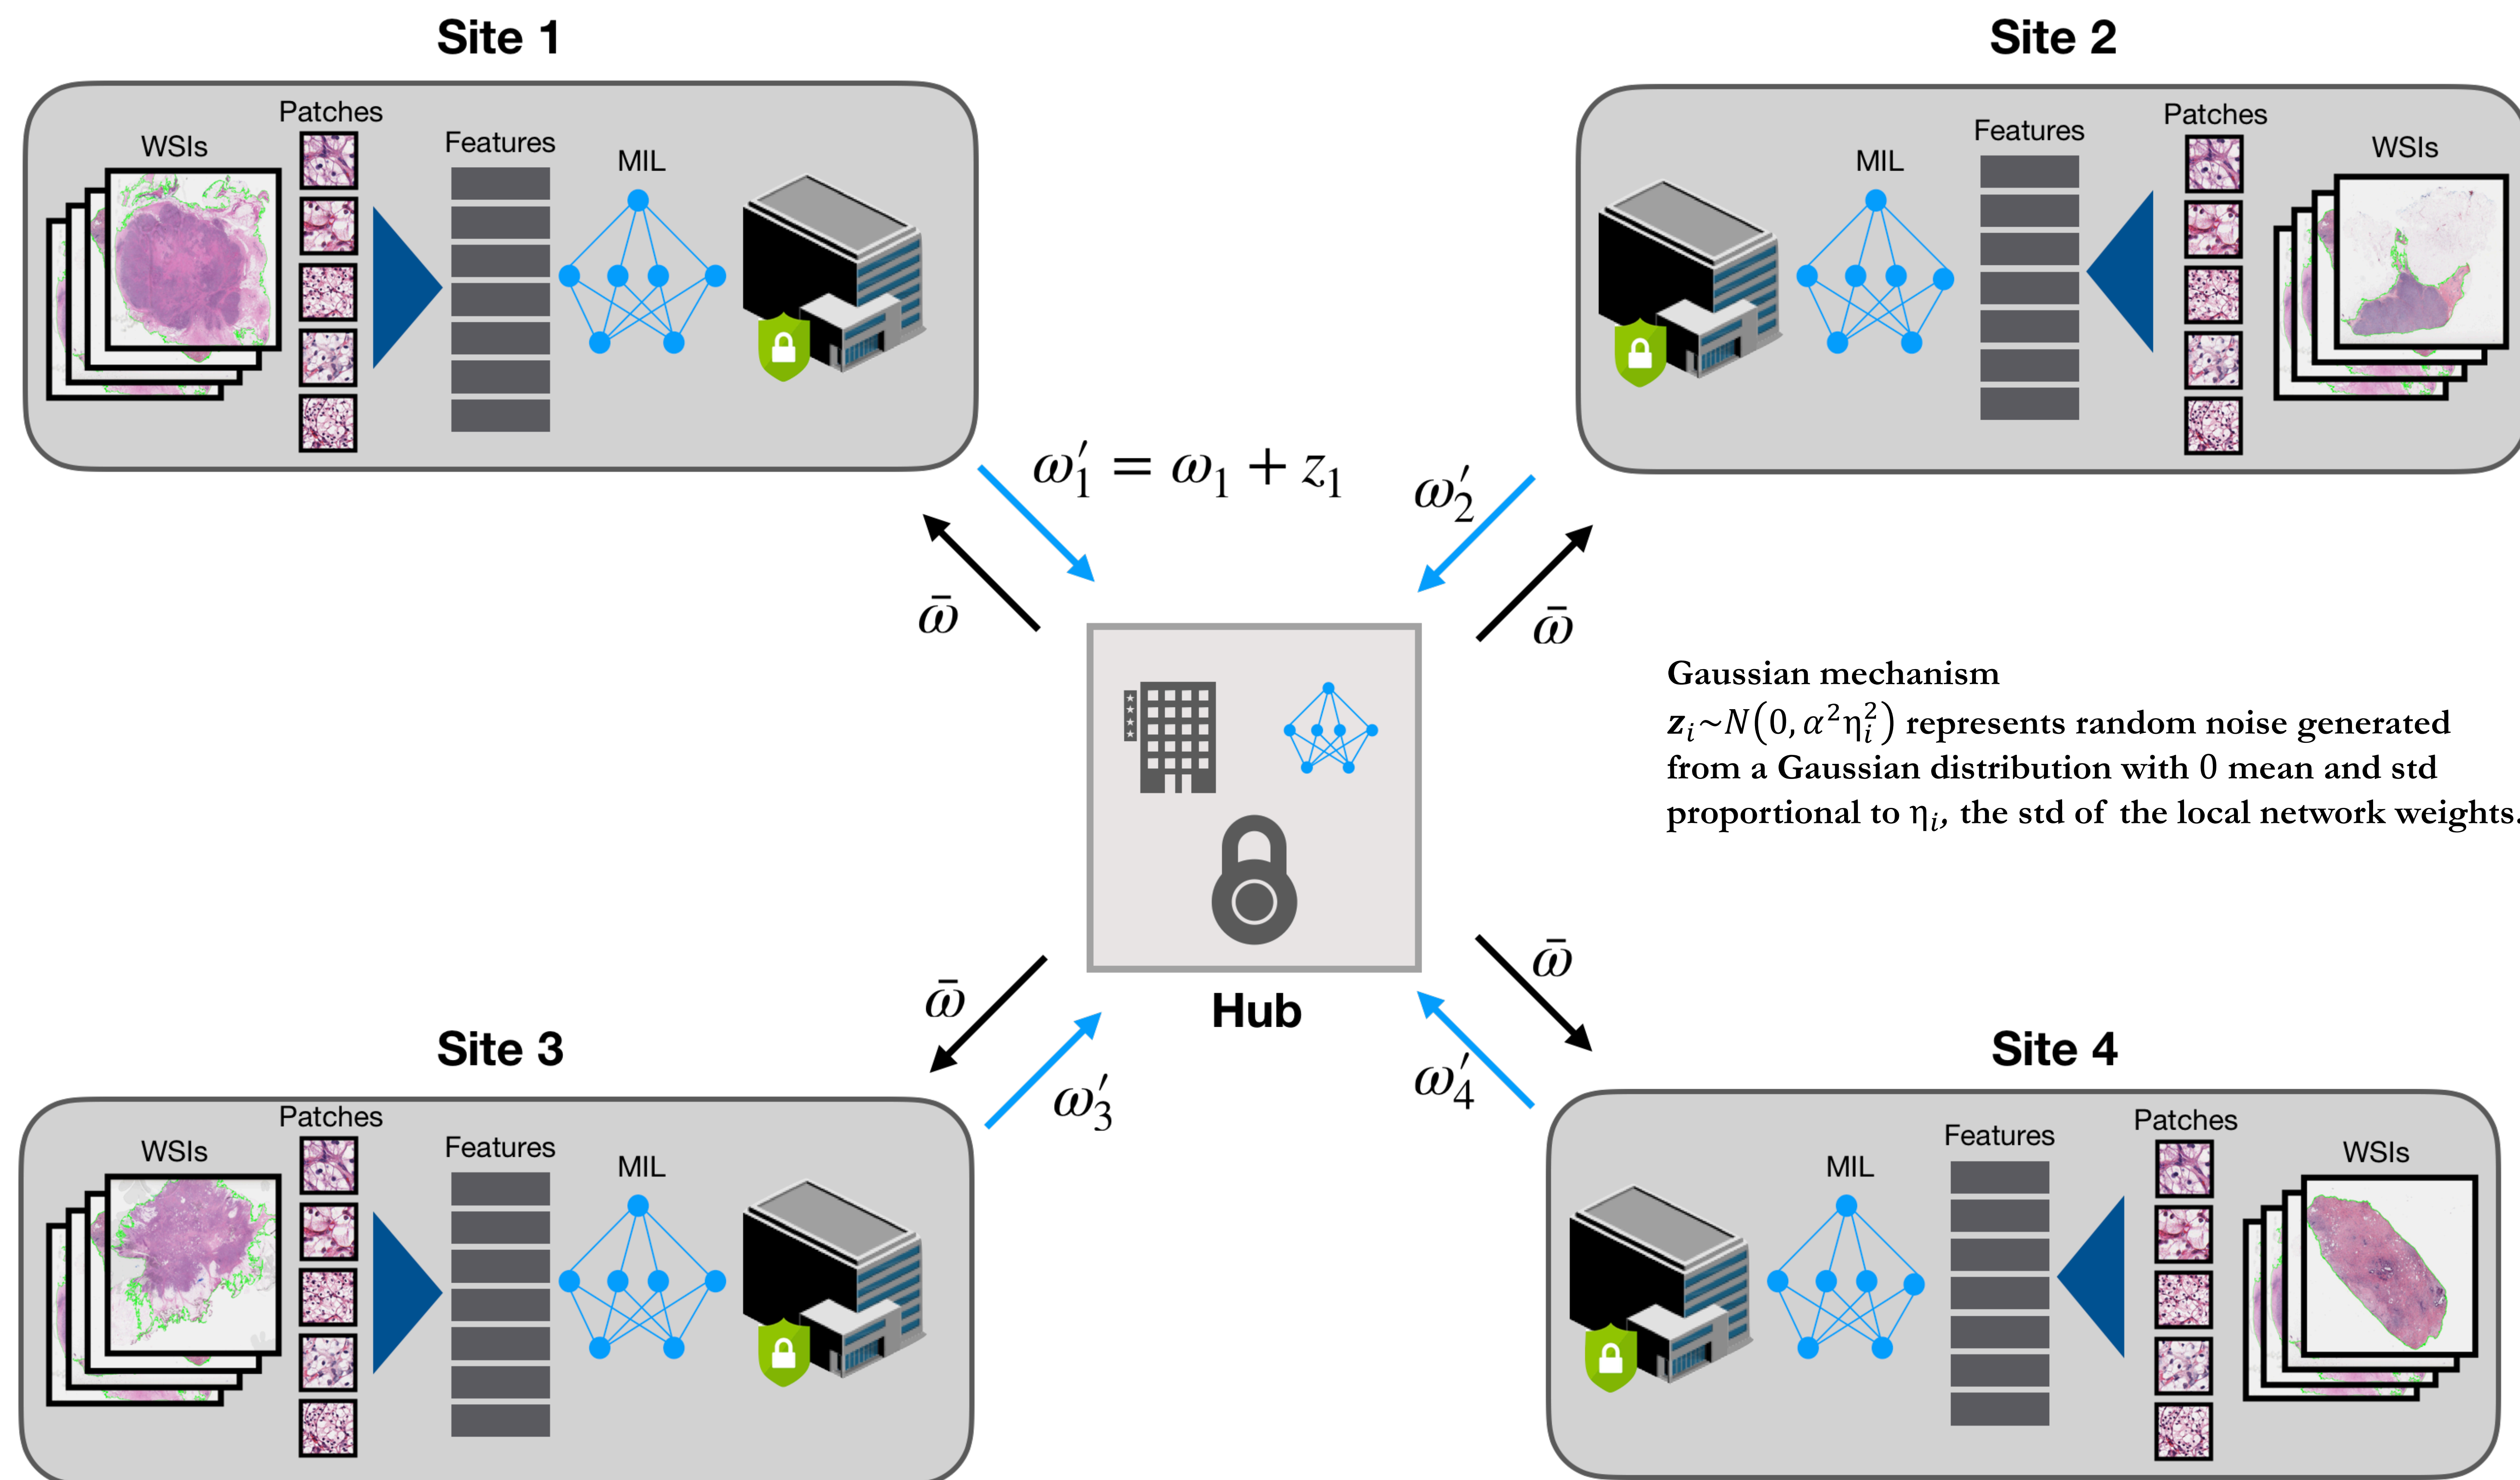

Depending on the task, the last layer of the network either predicts class-probability scores (classification) or models the hazard function (survival prediction):

$$f_{hazard}(r | \mathbf{h}_{bag_j}) = P(T_j = r | T_j \geq r, \mathbf{h}_{bag_j})$$

For classification, the network is supervised via the cross-entropy loss, and for survival, we used the nll loss given below, where  $f_{surv}$  is the survival function,  $c_j$  the censorship status and  $Y_j$  the ground truth discrete follow-up time:

$$L = -l = -c_j \cdot \log(f_{surv}(Y_j | \mathbf{h}_{bag_j})) - (1 - c_j) \cdot \log(f_{surv}(Y_j - 1 | \mathbf{h}_{bag_j})) - (1 - c_j) \cdot \log(f_{hazard}(Y_j | \mathbf{h}_{bag_j}))$$

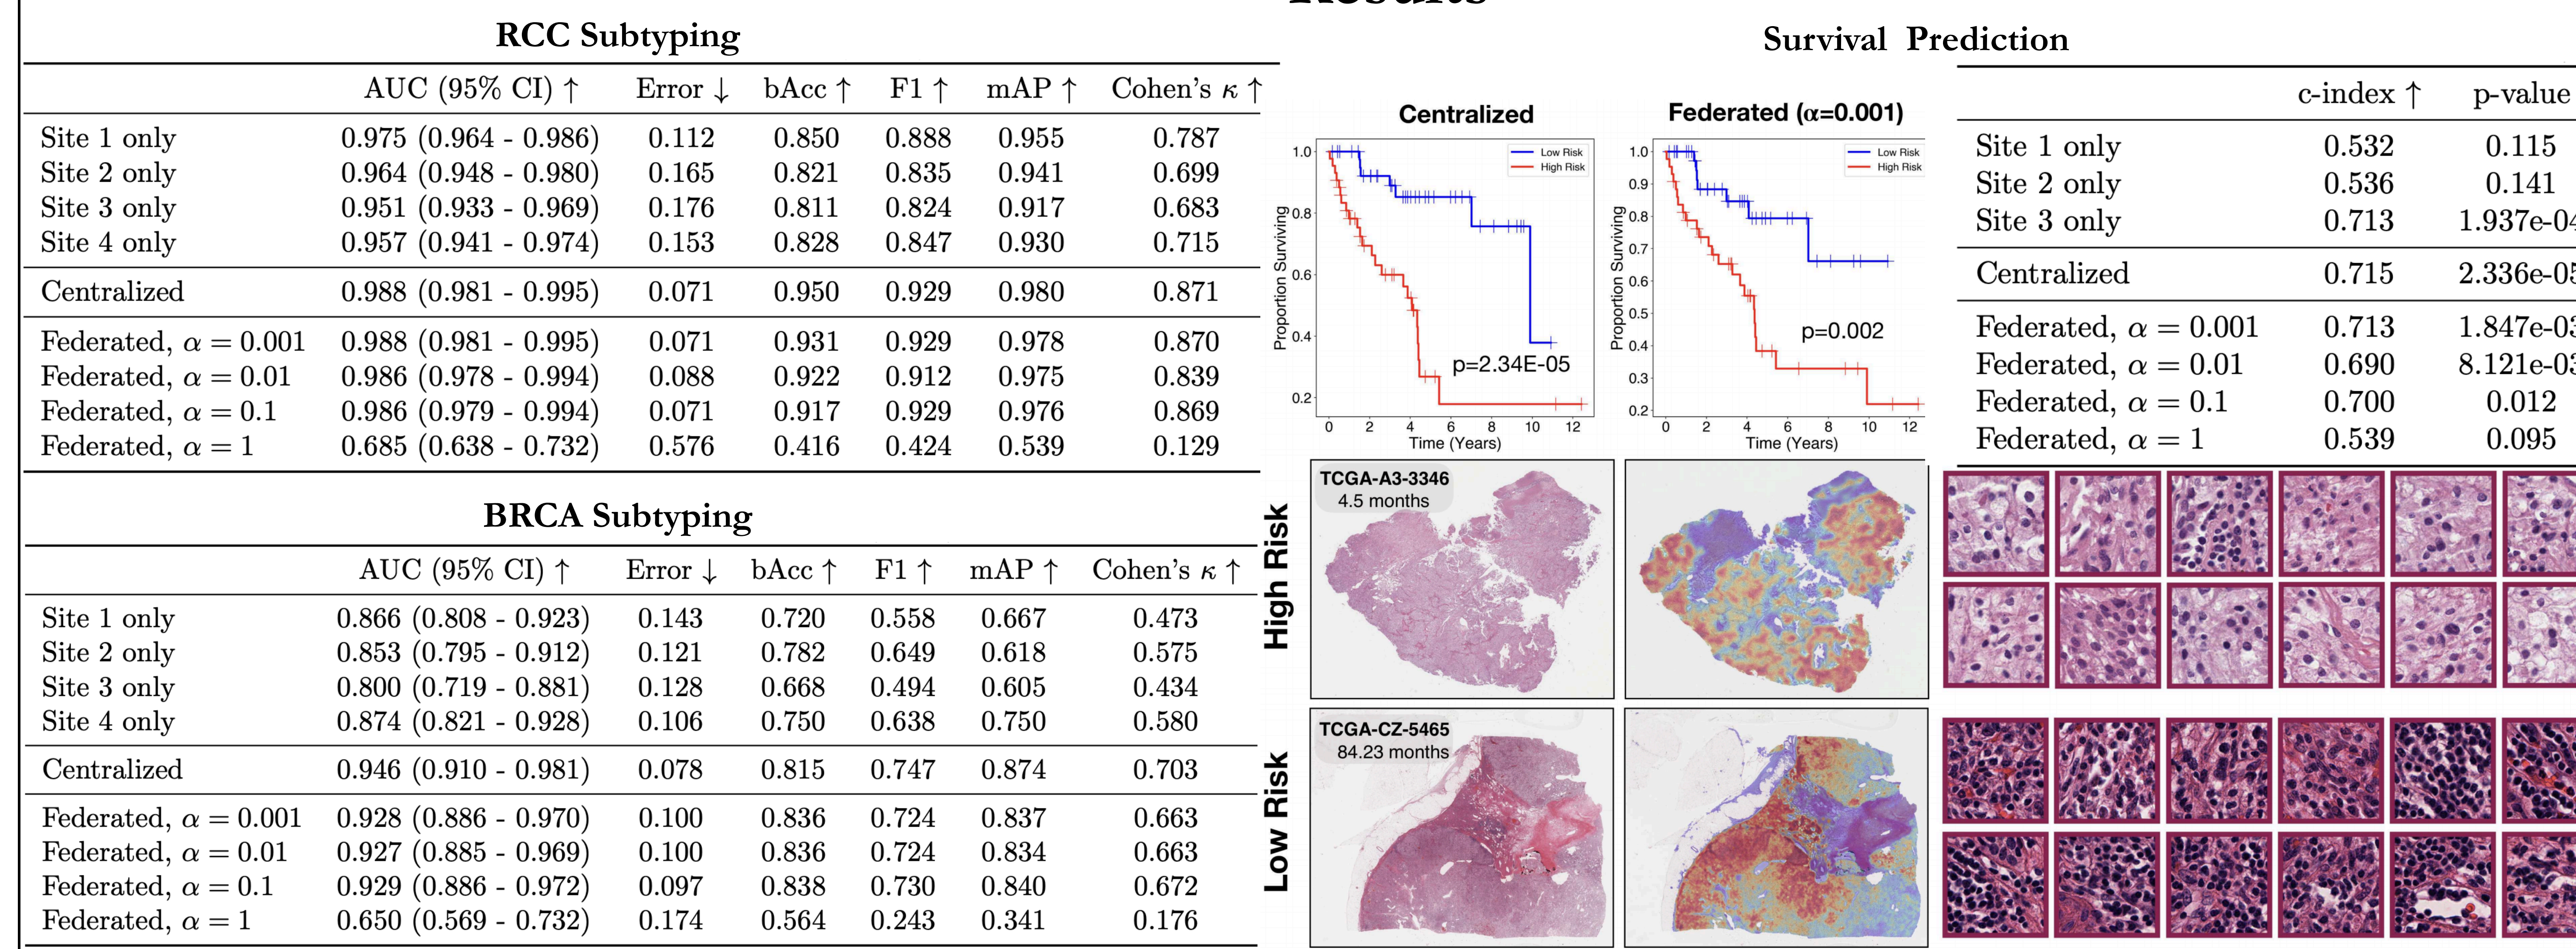

## Federated Learning for Weakly-supervised Classification and Survival Prediction on Whole Slide Images

### Experimental Setup

- Classification tasks:
  - Renal cell carcinoma (RCC) histologic subtyping into clear cell (CCRCC), papillary (PRCC) and chromophobe (CHRCC)
  - Breast invasive carcinoma (BRCA) histologic subtyping into ductal (IDC) and lobular (ILC)
- Survival prediction:
  - CCRCC survival prediction and risk-based patient stratification
- Datasets:
  - TCGA-KIRC (519 WSIs), TCGA-KIRP (297 WSIs), TCGA-KICH (121 WSIs), TCGA-BRCA (1056 WSIs), BWH In-house (247 RCC WSIs and 1070 BRCA WSIs)
  - TCGA datasets are separated into multiple groups of institutions based on tissue source sites
- Learning algorithms:
  - Privacy-preserving federated learning using federated averaging + Gaussian mechanism with adjustable hyperparameter  $\alpha$
  - Attention multiple instance learning based classification (cross-entropy loss) and survival prediction (negative log-likelihood loss for discrete survival model).
  - Adam optimizer: 2e-4 lr, 1e-5 weight-decay
- Evaluation:
  - 70/15/15 train, val, test partitions
  - AUC, Error, bACC (balanced accuracy), F1, mAP, Cohen's  $\kappa$
  - C-index, log-rank test

### Results

### Discussion

- We generalize attention-based multiple instance learning to weakly-supervised federated learning for multi-institutional computational pathology on WSIs, requiring only slide-level/patient-level labels
- Our approach is privacy-preserving, interpretable, generally applicable to both classification and survival prediction and can easily be used on large WSI datasets
